food, drink, furniture, stool, bar

Article Body:

For many years aluminium has been used in the construction of many styles of furniture everything from a café chair to a bar stool. In a lot of ways, aluminium is the ideal substance for anything that needs to be lightweight, strong, and easy to work with in the manufacturing process. In comparison to wood plastic and a lot of metal style bar stools aluminium hold the lead for light weight, durability, and accessibility to others.

As with everything in the manufacturing industry, cost is a major thing and is this issue that has the biggest determination over the overall price at the end. So with this point in mind it would be worth mentioning how this point help will help the consumer in 2 ways.

First reason is, because aluminium is so easy to produce and the cost to the manufacturer is low, the customer never really has to pay extra for a bar stool, it does not unjustifiably increase the end product's price.

The second would have to do with the shipping costs, because aluminium is so much lighter than any other metal that would be used to make bar stools or even wood the shipping costs would be less. Unless you can find a good deal and get free shipping then the heavier materials that some bar stools would cost an absolute fortune to ship especially if it is to be shipped overseas.

Another advantage that aluminium makes doable is its ability to copy the

polished stainless steel effect. Stainless steel is a far heavier and more costly metal, both of these points will mean increased costs on such items as barstools. Since aluminium can be made to closely match any other metal on the market and if you consider that point, is there any reason that that you should ever choose a heavier metal for your bar stool.

From the barstool manufacturer's perspective, aluminium is an attractive metal for all the reasons listed above, mainly for its design applications and many weight properties.
