When do you need data recovery help? There are going to be those times when you
just delete the wrong file or lose your data when your computer somehow loses
power. But, what about the event of hard drive failure? What in the world can
you do then to repair the lost data that you have? There are several things
that you will want to do to get that data back. Luckily, today's computers are
often powerful tools that have some helpful strategies to prevent and restore
these problems.

Step 1: Determine what has happened. If you find that you have an error
message on your screen, jot it down. That is a clue as to what happened. You
may need to contact your provider to access help. If your data is gone, and you
can not find it in your recycle bin, keep track of what happened.

Step 2: Try your recovery system. Most computers today have a back up that
will save what you are working on as you are working on it. This can be helpful
in providing you with the necessary help you need in finding files that are just
lost.

Step 3: If these things are not enough to restore any of the data that you have
lost, or you have had a hard drive crash, it is essential to use a good quality
data recovery product or software tool to help in restoring at least some of it.
If your system does not come with this, which most do not, you will need to

purchase it. But, it can help to restore data that is far more worthwhile to you when you think that everything is gone.

Even with data recovery software and the best computer technicians, not everything can be successfully recovered. If nothing else, you can learn from this and keep everything on your computer backed up onto a removable disk. Consider doing this at least weekly if you use your computer for quite a bit of storage, monthly otherwise.
